Recall “ $\text{psp}(n)$ ” means $2^{n-1} \equiv 1 \pmod{n}$, n composite and odd. We let p, q, ℓ always denote odd primes. Let

$$P_2(x) = \# \{n \leq x : n = pq, p < q, \text{psp}(n)\}.$$

Conjecture: Let

$$\delta(m) = \begin{cases} 2 & \text{if } 4 \mid m \\ 1 & \text{otherwise} \end{cases}$$

$$\rho(m) = \prod_{\ell \mid m} \frac{\ell - 1}{\ell - 2}$$

$$T = 2 \prod_{\ell} \frac{1 - 2/\ell}{(1 - 1/\ell)^2} \approx 1.320323632 \dots$$

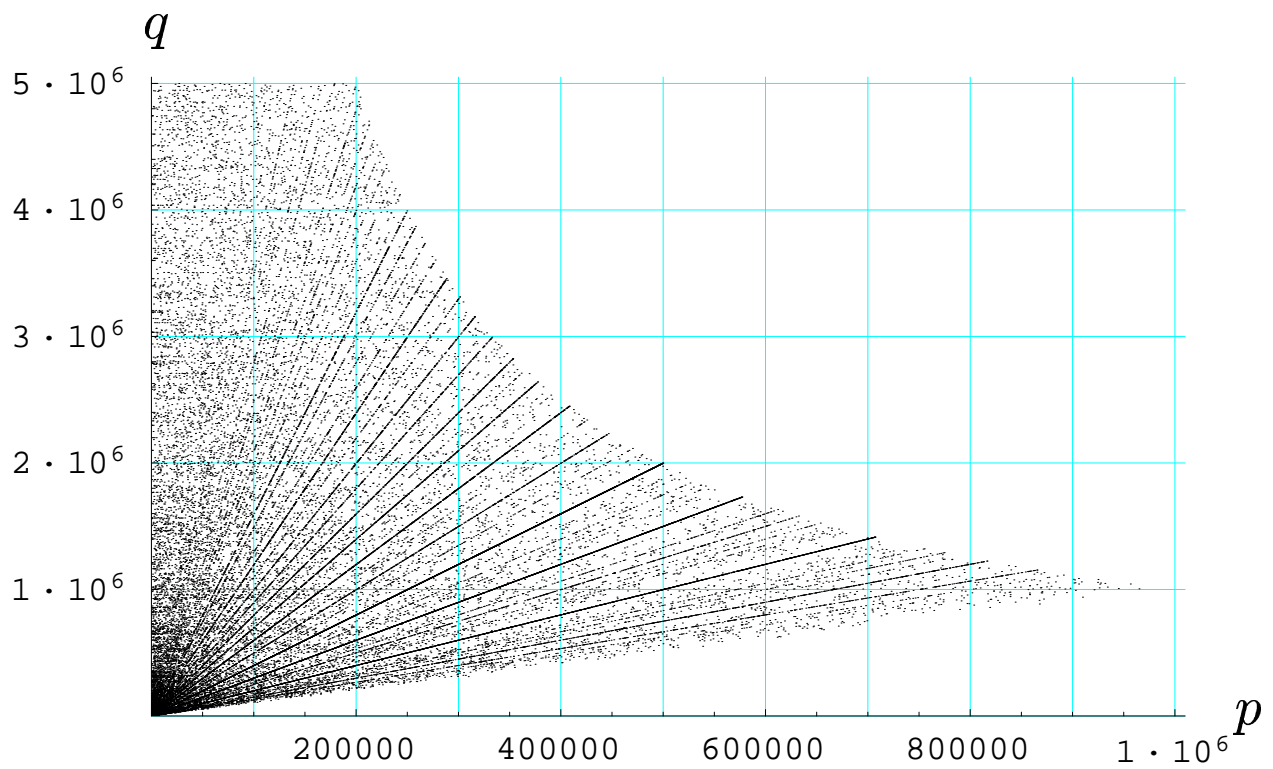

$$C = 4T \sum_{a \geq 1} \sum_{\substack{b > a \\ \gcd(a,b)=1}} \frac{\delta(ab) \rho(ab(b-a))}{(ab)^{3/2}} \approx 30.03 \dots$$

Then

$$P_2(x) \sim C \sqrt{x} / \ln^2(x)$$

The Big Picture

Pseudoprimes $pq < 10^{12}$ with $q < 5 \cdot 10^6$.

Overview

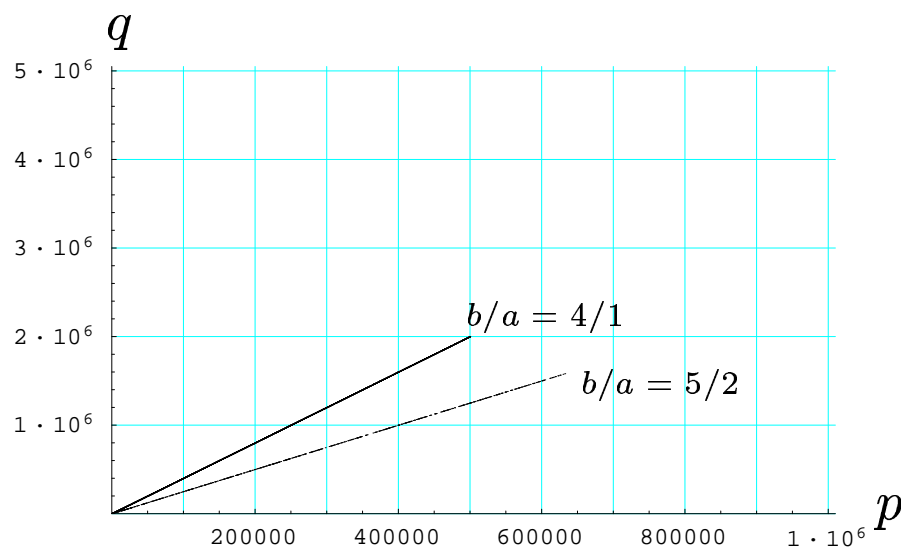

Fix $a, b, a \neq b, \gcd(a, b) = 1$ and first estimate

$$\# \left\{ p \leq z : \frac{q-1}{p-1} = \frac{b}{a}, p \text{ \& } q \text{ prime} \right\},$$

then estimate

$$\# \left\{ p \leq z : \frac{q-1}{p-1} = \frac{b}{a}, p \text{ \& } q \text{ prime, psp}(pq) \right\}.$$

Finally, sum over all a, b .

Pairs of Primes on Lines

Conjecture: (Hardy and Littlewood, [HL19], [HL23, Conjecture D])

$$\# \left\{ p \leq z : \frac{q-1}{p-1} = \frac{b}{a} \right\} \sim \frac{T\rho(ab(b-a))}{a} \frac{z}{\ln^2(z)}$$

where (again) ℓ runs through odd primes,

$$T = 2 \prod_{\ell} \frac{1 - 2/\ell}{(1 - 1/\ell)^2} \approx 1.320323632 \dots$$

and

$$\rho(m) = \prod_{\ell|m} \frac{\ell - 1}{\ell - 2}$$

Fact: Given odd primes p, q , with $\frac{q-1}{p-1} = \frac{b}{a}$, then

$$\text{psp}(pq) \iff 2^{(p-1)/a} \equiv 1 \pmod{p} \ \& \ 2^{(q-1)/b} \equiv 1 \pmod{q}.$$

The Chebotarëv density theorem implies, for a “random” prime $p \equiv 1 \pmod{a}$, that

$$\text{Prob}[2^{(p-1)/a} \equiv 1 \pmod{p}] = \delta(a)/a.$$

Conjecture: (Density of pseudoprimes on lines)

$$\begin{aligned} \# \left\{ p \leq z : \frac{q-1}{p-1} = \frac{b}{a}, \text{psp}(pq) \right\} \\ \sim \frac{T \delta(ab) \rho(ab(b-a))}{a^2 b} \frac{z}{\ln^2(z)} \end{aligned}$$

Since $pq \leq x$ gives $p \leq z$ with $z \sim \sqrt{ax/b}$ we expect

$$\begin{aligned} \# \left\{ pq \leq x : \frac{q-1}{p-1} = \frac{b}{a}, \text{psp}(pq) \right\} \\ \sim \frac{4T \delta(ab) \rho(ab(b-a))}{(ab)^{3/2}} \frac{\sqrt{x}}{\ln^2(x)} \end{aligned}$$

Summing over Lines

Summing over a, b suggests our conjectured formula:

$$P_2(x) \sim C\sqrt{x}/\ln^2(x)$$

with

$$C = 4T \sum_{a \geq 1} \sum_{\substack{b > a \\ \gcd(a,b)=1}} \frac{\delta(ab) \rho(ab(b-a))}{(ab)^{3/2}}.$$

Quality of our Conjectures

Pseudoprimes on a line. $b/a = 3/2$, showing

$$N(z) := \# \left\{ p \leq z : \frac{q-1}{p-1} = \frac{b}{a}, \text{ psp}(pq) \right\}$$

versus $z/\ln^2(z)$ and versus

$$\int_0^z \frac{1}{\ln(t) \ln(bt/a)} dt.$$

z	$N(z)$	$N(z) \ln^2(z)/z$	$N(z)/\int$
10^4	27	0.2290	0.1774
10^6	1285	0.2453	0.2125
10^8	71697	0.2433	0.2200
∞	...	0.2201	0.2201

Counts of pseudoprimes versus $\sqrt{x}/\ln^2(x)$.

x	$P_2(x)$	$P_2(x) \ln^2(x)/\sqrt{x}$
10^4	11	9.331
10^5	34	14.251
10^6	107	20.423
10^7	311	25.550
10^8	880	29.860
10^9	2455	33.340
10^{10}	6501	34.468
10^{11}	17207	34.908
10^{12}	46080	35.181
10^{13}	123877	35.100
∞	...	30.03...

Carmichael Numbers with k Prime Factors

Our conjecture on the density of pseudoprimes with two prime factors is closely related to a conjecture of Granville and Pomerance on the density of Carmichael numbers with k prime factors [GP]. Recall that n is a Carmichael number if n is composite and $a^n \equiv a \pmod{n}$ for all $a \in \mathbb{N}$.

Conjecture: Let $C_k(x)$ be the counting function for Carmichael numbers with k prime factors, $k \geq 3$. Then

$$C_k(x) \sim \tau_k x^{1/k} / \ln^k(x)$$

for some $\tau_k > 0$.
